

Smart cradle monitoring system

ABSTRACT

Parents always worry about the safety, health, and comfort of their babies, but it can be difficult to keep an eye on them at all times with today's busy work and home life. In those of ordinary cradle there is no intelligence or automatic rest, with the consequence that babies are in danger of becoming winks. To address this issue, in this paper, we present a Smart Cradle Monitoring System through sensor and IoT to automatic the care process and to monitor in real time. It is a system that employs a set of sensors to measure and record the vital signs: baby motion, cry, and environment (temperature and humidity). The detected signals are formatted by a microcontroller, then the microcontroller can modulate a responding act such as shaking the cradle, slightly shaking the cradle, sounding lullaby, etc to comfort the child.

While, it also gives a live alert to parents anywhere on their Smartphones using an accompanying app, so they can view the child remotely and respond. The condition of the baby can be therefore monitored continuously without the need for the attention of the carer for different activities. Reasonable, energy economizing and convenient to use, It is for both home use and clinical use. In medical institutions it can help neonatal unit staff by announcing early signs of changing babies activity. It reduces the anxiety and workload of custodians at home, and enriches the security device system of a child. In conclusion, the Smart Cradle Monitoring System brings in the tradition of baby care alongside the automation, serving as a dependable, budget-friendly and an intelligent step towards making baby care safe and parents carefree.
